

## Drying out the Plants

In order to measure the plants' weights in grams, we took multiple steps in order to ensure an accurate measurement. First, we put the plants on a scale, weighing them with their respective groupings. For example, the soybeans that were in the second bag that were exposed to full light were measured together and so on. After marking down their weights, the plants were placed in an incubator to be dried out. After drying out, the plants' measurements were taken again and with that we can see how much of the plant's weight was simply water weight.
